Unbounded Binary Search Example (Find the point where a monotonically increasing function becomes positive first time)

Given a function 'int f(unsigned int x)' which takes a **non-negative integer** 'x' as input and returns an **integer** as output. The function is monotonically increasing with respect to value of x, i.e., the value of f(x+1) is greater than f(x) for every input x. Find the value 'n' where f() becomes positive for the first time. Since f() is monotonically increasing, values of f(n+1), f(n+2),... must be positive and values of f(n-2), f(n-3), .. must be negative.

Find n in O(logn) time, you may assume that f(x) can be evaluated in O(1) time for any input x.

A **simple solution** is to start from i equals to 0 and one by one calculate value of f(i) for 1, 2, 3, 4 .. etc until we find a positive f(i). This works, but takes O(n) time.

Can we apply Binary Search to find n in $O(\text{Log}n)$ time? We can't directly apply Binary Search as we don't have an upper limit or high index. The idea is to do repeated doubling until we find a positive value, i.e., check values of $f(i)$ for following values until $f(i)$ becomes positive.

```
f(0)
f(1)
f(2)
f(4)
f(8)
f(16)
f(32)
....
....
f(high)
```

Let 'high' be the value of i when $f(i)$ becomes positive for first time.

Can we apply Binary Search to find n after finding 'high'? We can apply Binary Search now, we can use 'high/2' as low and 'high' as high indexes in binary search. The result n must lie between 'high/2' and 'high'.

Number of steps for finding 'high' is $O(\text{Log}n)$. So we can find 'high' in $O(\text{Log}n)$ time. What about time taken by Binary Search between high/2 and high? The value of 'high' must be less than $2*n$. The number of elements between high/2 and high must be $O(n)$. Therefore, time complexity of Binary Search is $O(\text{Log}n)$ and overall time complexity is $2*O(\text{Log}n)$ which is $O(\text{Log}n)$.

```
#include <stdio.h>
int binarySearch(int low, int high); // prototype

// Let's take an example function as f(x) = x^2 - 10*x - 20
// Note that f(x) can be any monotonocally increasing function
int f(int x) { return (x*x - 10*x - 20); }

// Returns the value x where above function f() becomes positive
// first time.
int findFirstPositive()
{
    // When first value itself is positive
    if (f(0) > 0)
        return 0;

    // Find 'high' for binary search by repeated doubling
    int i = 1;
    while (f(i) <= 0)
        i = i*2;

    // Call binary search
    return binarySearch(i/2, i);
}

// Searches first positive value of f(i) where low <= i <= high
int binarySearch(int low, int high)
{
    if (high >= low)
    {
```

```

int mid = low + (high - low)/2; /* mid = (low + high)/2 */

// If f(mid) is greater than 0 and one of the following two
// conditions is true:
// a) mid is equal to low
// b) f(mid-1) is negative
if (f(mid) > 0 && (mid == low || f(mid-1) <= 0))
    return mid;

// If f(mid) is smaller than or equal to 0
if (f(mid) <= 0)
    return binarySearch((mid + 1), high);
else // f(mid) > 0
    return binarySearch(low, (mid - 1));
}

/* Return -1 if there is no positive value in given range */
return -1;
}

```

```

/* Driver program to check above functions */
int main()
{
    printf("The value n where f() becomes positive first is %d",
        findFirstPositive());
    return 0;
}

```

Output:

The value n where f() becomes positive first is 12

If we had multiplied it by 3, instead of 2 it wouldn;t had made a difference right?

  • Reply • Share ▸**madhu** • 10 months ago

please check the code provided in the link below...can anyone figure out the time complexity?

  • Reply • Share ▸**madhu** • 10 months ago<http://ideone.com/cBwkbp>  • Reply • Share ▸**<HoldOnLife!#>** → **madhu** • 9 months ago

```
int binary_search(int low,int high)
```

```
{  
    int candidate= -1;  
    int mid;  
    while(low <= high)  
    {  
        mid = low +(high-low)/2;  
        if(f(mid) >0 )  
        {  
            candidate = mid;  
            high = mid-1;  
        }  
        else  
            low = mid+1;  
    }  
    return candidate;  
}
```

so if the function does not return any positive value for input up till INT_MAX, then will it not get stuck in an infinite loop ?

We need to change this

```
while (f(i) <= 0)
```

^ | v · Reply · Share ›

**raghvendra** · 2 years ago

```
#include<stdio.h>
#include<iostream>
#include<cmath>
using namespace std;
#define p 1e-6
double value(double x)
{
    return 2*x+5;
}
double binary(double low,double high)
{
    double mid;
    while(abs(high-low)>p)
    {
        mid=low+(high-low)/2;
        if(abs(value(mid))<=p)return mid;
        else if(value(mid)>0)
            high=mid;
```

We can do a binary search for a value of mid where,
if mid satisfies the condition $f(\text{mid}) * f(\text{mid}+1) < 0$, we return mid+1.
if mid satisfies the condition $f(\text{mid}) * f(\text{mid}-1) < 0$, we return mid.

because $(-ve) * (-ve) = (+ve)$ and $(+ve) * (+ve) = (+ve)$ only at the point of transition there is a negative product.

**darkpassenger** · 2 years ago

can you tell any case when binary search returns -1 i.e there is no element which is positive after checking in the function find first positive that positive element exists.

^ | v · Reply · Share ›

**Abhinav Aggarwal** · 2 years ago

If you do that, then the gap between the subsequent iterations will increase when you get the interval. Suppose that now you make gap $3*i$ from i . Then you would need to apply binary search in those $2i$ elements.

^ | v · Reply · Share ›

**Anshul Gupta** · 2 years ago

This is more like newton-raphson method which terminates for the first +ve $f(x)$.

^ | v · Reply · Share ›

**Manish** · 2 years ago

We can make use of $f'(x)$ (rate of change of $f(x)$ at x) for computing the amount by which we want to increase i . I think it will significantly reduce complexity.

couldnt figure out how to use it...:(

**GeeksforGeeks** · 2 years ago

Please take a closer look at the article. Also, take few examples. It is simple, no big deal. It must become clear. Note few things.

1) Function must be monotonically increasing, i.e., $f(0) < f(1) < f(2) < \dots < f(n) < f(n+1) < \dots$

2) We want to find out FIRST value i such that $f(i)$ is positive where i may be any integer greater than or equal to 0.

^ | v · Reply · Share ›

**Mukul Taneja** · 2 years ago

I cannot understand two things.

why these two assumptions are made?

1. The result n must lie between 'high/2' and 'high'.

2. The value of 'high' must be less than $2*n$?

Plz explain.....

^ | v · Reply · Share ›

**Itachi Uchiha** → Mukul Taneja · 3 months ago

Suppose for i , $f(i)$ is the last encountered which is negative such that $f(2*i)$ is positive. thus we pass $2*i$ as high and i as high/2 which is low.

2 ^ | v · Reply · Share ›

**Priyank Jain** · 2 years ago

why not use a higher increment?

So, instead of.

· · · · ·

$i = i \ll 2$,

why not use something like $i *= 3$ or even 4?

^ | v • Reply • Share ›

zzerr → Priyank Jain • a year ago

then the range between low and high is bigger, and we can simple use bit manipulation to set $i=i*2$ by sift $i = i \ll 2$, it is faster as well

md03 • 2 years ago

```
if (f(mid) > 0 && (mid == low || f(mid-1) <= 0))
    return mid;
```

Correct me if I am wrong admin:

Since the function is monotonically increasing, the condition:

$\text{if}(f(\text{mid}) > 0 \ \&\& \ f(\text{mid}-1) \leq 0)$

is sufficient.

$\text{mid} == \text{low}$ is satisfied when the high is equal to low or $\text{high} = \text{low} + 1$. Even in this case $f(\text{mid}-1) \leq 0$ is satisfied. Also, $\text{mid}-1$ will always be non-negative since $\text{mid}=0$ will never be tested here, since it has already been tested in the first step of the "int findFirstPositive()" function.

^ | v • Reply • Share ›

np → md03 • 10 months ago

$\text{if}(f(\text{mid}) > 0 \ \&\& \ f(\text{mid}-1) \leq 0)$ condition is sufficient

^ | v • Reply • Share ›

kartik → md03 • 2 years ago

' $\text{mid} == \text{low}$ ' is also needed. Consider the case when $\text{low} = 0$, $\text{high} = 0$ or when $\text{low} = 5$ and $\text{high} = 6$.

^ | v • Reply • Share ›

md03 → kartik • 2 years ago

In case of $\text{low}=0$ and $\text{high}=0$, $\text{mid}=0$. If first positive value is at index 0, it will be returned at this point:

$\text{if } (f(0) > 0)$

return 0;

If the first positive value is not at index 0, thus the first condition $(f(\text{mid}) > 0)$ is found false, the second $(f(\text{mid}-1) \leq 0)$ shall not be checked.

In the case when $\text{low}=5$ and $\text{high}=6$, $\text{mid}=5$

if $f(5)$ is the first positive, then $f(4)$ is negative and hence condition $f(\text{mid}) > 0 \ \&\& \ f(\text{mid}-1) \leq 0$ is satisfied.

Unbounded Binary Search Example (Find the point where a monotonically increasing function becomes positive first time) - GeeksforGeeks

If $f(3)$ is the first positive, then $f(4)$ is negative and hence condition $f(\text{mid}) < 0 \ \&\&$
 $f(\text{mid}-1) \leq 0$ is enough.

If $f(5)$ is not the first positive then $f(4)$ is also positive, again the aforesaid condition is sufficient.

Ishwar Jindal • 2 years ago

what about using a step variable. we will not need special binary search function then while still doing it in $\log(n)$. here is the code:

```
FindFirstPos() {
```

```
    int step=0, i=1;.
```

```
    if(f(0)>0) return 0;.
```

```
    while(1) {.
```

```
        if(f(i)<0) {.
```

```
            if(! step) step=1;
```

```
            else step*=2;
```

```
            i+=step;
```

```
        }.
```

```
        if(f(i)>=0) {.
```

```
            if(step==1) return i;.
```

```
            else {
```

```
                step/=2;.
```

```
                i-=step;.
```

```
            }
```

```
        }.
```

```
    }.
```

```
}
```

Please let me know if there seem some bug.
