## Multiply two polynomials

Given two polynomials represented by two arrays, write a function that multiplies given two polynomials.

Example:

Input:  $A[] = \{5, 0, 10, 6\}$

$B[] = \{1, 2, 4\}$

Output:  $prod[] = \{5, 10, 30, 26, 52, 24\}$

The first input array represents " $5 + 0x^1 + 10x^2 + 6x^3$ "

The second array represents " $1 + 2x^1 + 4x^2$ "

And Output is " $5 + 10x^1 + 30x^2 + 26x^3 + 52x^4 + 24x^5$ "

**We strongly recommend to minimize your browser and try this yourself first.**

A simple solution is to one by one consider every term of first polynomial and multiply it with every term of second polynomial. Following is algorithm of this simple method.

```
multiply(A[0..m-1], B[0..n-1])
```

- 1) Create a product array prod[] of size m+n-1.
- 2) Initialize all entries in prod[] as 0.
- 3) Traverse array A[] and do following for every element A[i]  
 ...(3.a) Traverse array B[] and do following for every element B[j]  
       prod[i+j] = prod[i+j] + A[i] \* B[j]
- 4) Return prod[].

The following is C++ implementation of above algorithm.

```
// Simple C++ program to multiply two polynomials
```

```
#include <iostream>
```

```
using namespace std;
```

```
// A[] represents coefficients of first polynomial
```

```
// B[] represents coefficients of second polynomial
```

```
// m and n are sizes of A[] and B[] respectively
```

```
int *multiply(int A[], int B[], int m, int n)
```

```
{
```

```
    int *prod = new int[m+n-1];
```

```
    // Initialize the product polynomial
```

```
    for (int i = 0; i<m+n-1; i++)
```

```
        prod[i] = 0;
```

```
    // Multiply two polynomials term by term
```

```
    // Take every term of first polynomial
```

```
    for (int i=0; i<m; i++)
```

```
    {
```

```
        // Multiply the current term of first polynomial
```

```
        // with every term of second polynomial.
```

```
        for (int j=0; j<n; j++)
```

```
            prod[i+j] += A[i]*B[j];
```

```
    }
```

```
    return prod;
```

```
}
```

```
// A utility function to print a polynomial
```

```
void printPoly(int poly[], int n)
```

```
{
```

```
    for (int i=0; i<n; i++)
```

```
    {
```

```
        cout << poly[i];
```

```
        if (i != 0)
```

```
            cout << "x^" << i ;
```

```
        if (i != n-1)
```

```
            cout << " + ";
```

```

    }
}

// Driver program to test above functions
int main()
{
    // The following array represents polynomial 5 + 10x^2 + 6x^3
    int A[] = {5, 0, 10, 6};

    // The following array represents polynomial 1 + 2x + 4x^2
    int B[] = {1, 2, 4};
    int m = sizeof(A)/sizeof(A[0]);
    int n = sizeof(B)/sizeof(B[0]);

    cout << "First polynomial is \n";
    printPoly(A, m);
    cout << "\nSecond polynomial is \n";
    printPoly(B, n);

    int *prod = multiply(A, B, m, n);

    cout << "\nProduct polynomial is \n";
    printPoly(prod, m+n-1);

    return 0;
}

```

## Output

```

First polynomial is
5 + 0x^1 + 10x^2 + 6x^3
Second polynomial is
1 + 2x^1 + 4x^2
Product polynomial is
5 + 10x^1 + 30x^2 + 26x^3 + 52x^4 + 24x^5

```

Time complexity of the above solution is  $O(mn)$ . If size of two polynomials same, then time complexity is  $O(n^2)$ .

## Can we do better?

There are methods to do multiplication faster than  $O(n^2)$  time. These methods are mainly based on [divide and conquer](#). Following is one simple method that divides the given polynomial (of degree  $n$ ) into two polynomials one containing lower degree terms (lower than  $n/2$ ) and other containing higher degree terms (higher than or equal to  $n/2$ )

Let the two given polynomials be  $A$  and  $B$ .  
 For simplicity, Let us assume that the given two polynomials are of same degree and have degree in powers of 2, i.e.,  $n = 2^i$

The polynomial ' $A$ ' can be written as  $A_0 + A_1 \cdot x^{n/2}$   
 The polynomial ' $B$ ' can be written as  $B_0 + B_1 \cdot x^{n/2}$

For example  $1 + 10x + 6x^2 - 4x^3 + 5x^4$  can be written as  $(1 + 10x) + (6 - 4x + 5x^2) \cdot x^2$

$$\begin{aligned}
 A * B &= (A_0 + A_1 * x^{n/2}) * (B_0 + B_1 * x^{n/2}) \\
 &= A_0 * B_0 + A_0 * B_1 * x^{n/2} + A_1 * B_0 * x^{n/2} + A_1 * B_1 * x^n \\
 &= A_0 * B_0 + (A_0 * B_1 + A_1 * B_0) x^{n/2} + A_1 * B_1 * x^n
 \end{aligned}$$

So the above divide and conquer approach requires 4 multiplications and  $O(n)$  time to add all 4 results. Therefore the time complexity is  $T(n) = 4T(n/2) + O(n)$ . The solution of the recurrence is  $O(n^2)$  which is same as the above simple solution.

The idea is to reduce number of multiplications to 3 and make the recurrence as  $T(n) = 3T(n/2) + O(n)$

### *How to reduce number of multiplications?*

This requires a little trick similar to [Strassen's Matrix Multiplication](#). We do following 3 multiplications.

```

X = (A0 + A1)*(B0 + B1) // First Multiplication
Y = A0B0 // Second
Z = A1B1 // Third

```

The missing middle term in above multiplication equation  $A_0 * B_0 + (A_0 * B_1 + A_1 * B_0) x^{n/2} + A_1 * B_1 * x^n$  can obtained using below.  
 $A_0 B_1 + A_1 B_0 = X - Y - Z$

So the time taken by this algorithm is  $T(n) = 3T(n/2) + O(n)$

The solution of above recurrence is  $O(n^{\lg 3})$  which is better than  $O(n^2)$ .

We will soon be discussing implementation of above approach.

There is a  $O(n \log n)$  algorithm also that uses Fast Fourier Transform to multiply two polynomials (Refer [this](#) and [this](#) for details)

**zeal** • 6 months ago

should be  $A * B = A0*B0 + (A0*B1 + A1*B0)x^{n/2} + A1*B1*x^n$

Hi. I need the code for the fast polynomial multiplication that uses 3, instead of 4, multiplications. Can you post that code?
